- Meteorological Station
- Pressure Transducer
- Stream Instrument Clusters

As Leaf Area Index (LAI) decreases with the thinning treatments, snow accumulation on the ground will increase, while evapotranspiration (ET) and snow retention in late spring will decrease.

A change in snow accumulation may be seen in the stream hydrograph as a change in the magnitude of the peak flow during peak snow melt.

Changes in snow retention, may translate to a change in timing of the recession limb of the hydrograph and the soil moisture curves.

Changes in ET may effect both the timing (how quickly base flow is reached or soil dries out) and the magnitude of late season base flow in the streams.
